

Genetic Networks

Miguel Román

miguel.romansanchez@uzh.ch

The genetic architecture of ecosystems

Genetic connectivity and structure within and between populations.

Studying genetic spatial variation is important for making informed decisions in conservation management efforts.

But what features can we study from it?

What processes shape it?

Basic concepts

Dispersal: movement of individuals from one location to another.

It can occur through a variety of mechanisms

- flight
- swimming
- movement of seeds or spores.

Basic concepts

Gene flow: movement of genes between different populations of the same species. Usually involves reproduction.

Basic concepts

Gene flow: movement of genes between different populations of the same species. Usually involves reproduction.

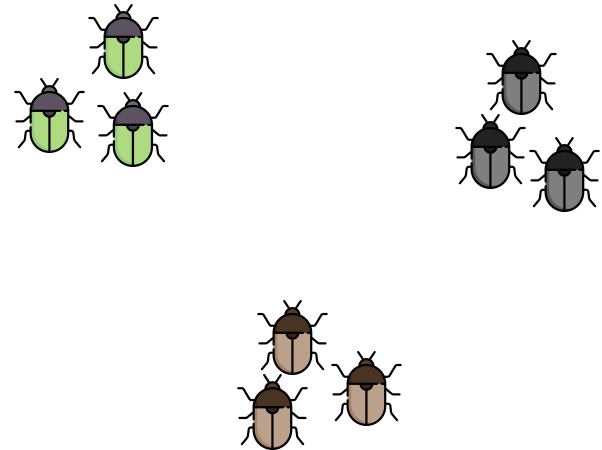

The genetic architecture of ecosystems

Different biological scales for genetic relatedness.

individual

population

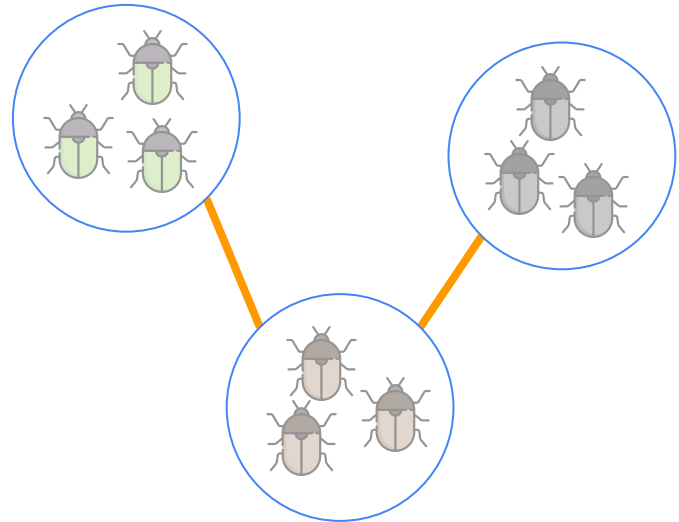

'Genetic networks'

Different biological scales for genetic relatedness.

individual

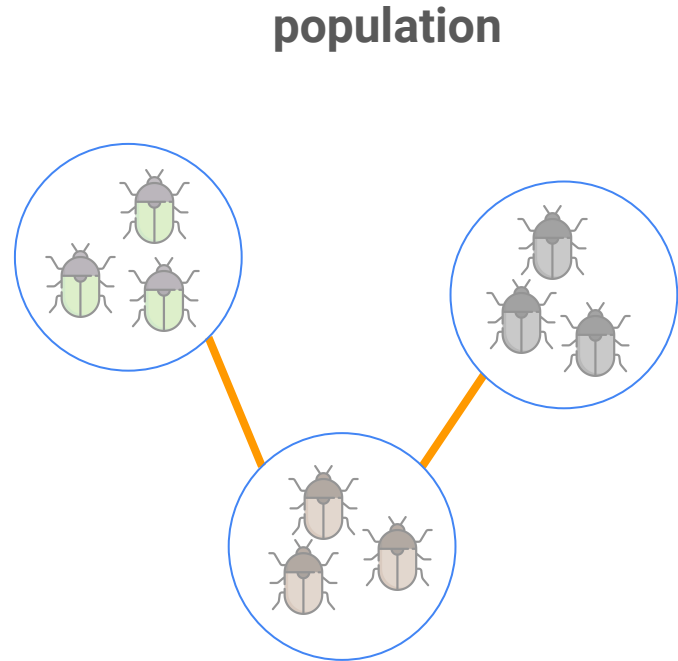

population

Population-based Genetic networks

Useful for studying gene flow.

Advantage: no a priori assumptions
about metapopulation structure.

Genetic networks

individual

population

Individual-based Genetic networks

individual

Useful for studying dispersal.

More definition, less bias

Network Construction

Genetic data: the raw material for building the networks.

Useful for estimating relatedness

- Microsatellites
- SNPs

Normal replication

loop in the new strand: gain

loop in the template strand: loss

Network Construction

	Population network	Individual network
Node	Genetic average of a sampling location.	Individual or clonal unit.
Edge weights	Genetic covariance between populations.	Relatedness (many different measures).
Node weights	Genetic covariance within the population.	-

Network Construction

Summary

Network Pruning

All nodes are similar to some degree → Fully connected network

To perform topological analyses we want to keep only meaningful links.

Network Pruning

All nodes are similar to some degree → Fully connected network

To perform topological analyses we want to keep only meaningful links.

BUT

What does 'meaningful' mean?

Network Pruning

different strategies → different resulting topologies

Population-based

- Minimum covariance
- Percolation point
- Fixed threshold

Individual-based

- Fixed threshold

Population-based Network Pruning

- Minimum covariance
- Percolation point
- Fixed threshold

Minimum set of links explaining total genetic variation among the populations.

Population-based Network Pruning

- Minimum covariance
- Percolation point
- Fixed threshold

Sequentially remove low similarity links until a percolation point is reached.

The point after which the network splits into two smaller components.

Population-based Network Pruning

- Minimum covariance
- Percolation point
- Fixed threshold

Remove all links lower than a particular value.

Network analysis

Different approaches:

- Network metrics (incl. modularity)
- Incorporate landscape features to nodes
- Multilayer analysis

Population-based Incorporating spatial features

Used for determining dispersal probability across the network.

Common for population-based networks.

Landscape information:

- Resistance surfaces
- Spatial distance

Network analysis - Hypothesis testing

- Null models
 - Random rewiring (edge swap)
 - Random re-weighting
- Assortativity coefficient: test for gene-flow barriers in the network
- Mantel Test:
 - Correlation Genetic distance \sim Physical distance
 - Compare layers in a multilayer network.
 - Compare edge weights with other measures.

Conservation Applications

Metapopulation structure → identify genetic units for planning management

Population structure → identify dispersal

Conservation Applications - Dispersal

Assortativity coefficient: checks if nodes with similar attributes are connected.

Useful to identify geographical barriers.

Suspected barrier

Conservation Applications - Gene Flow Structure

Genetic connectivity → studying gene flow

There are different types of keystone nodes:

- 'bridge nodes'
- 'hub nodes'

Conservation Applications - Gene Flow Structure

Betweenness centrality
to identify 'bridge nodes'

Conservation Applications - Gene Flow Structure

Node degree to identify
'hub nodes'

Conservation Applications - Gene Flow Structure

Eigenvector centrality to identify 'hub nodes'

Conservation Applications - Source/Sink Dynamics

Direction of gene flow \longrightarrow targeted conservation efforts

Source and **sink** nodes in the metapopulation

Conservation Applications - High Fitness Families

Multilayer network (population/region + individual) helps to identify:

- highly connected families
- regions of high reproductive output

This gives clues to detect:

- asymmetric breeding
- potential source and sink regions
